 City fixed effects α capture large rent level differences (e.g., Manhattan ≈ \$75/SF vs. Phoenix ≈ \$25/SF)

- Common slope estimates:
 - Positive for GDP and S&P 500 (though not all are statistically significant)
 - **Negative** for VIX
 - Slightly negative for the federal funds rate (suggesting higher rates may suppress rents)
- The model's R^2 is relevant → macro variables explain some rent variation
- City-specific dynamics are crucial

Bayesian Hierarchical Model (Partial Pooling)

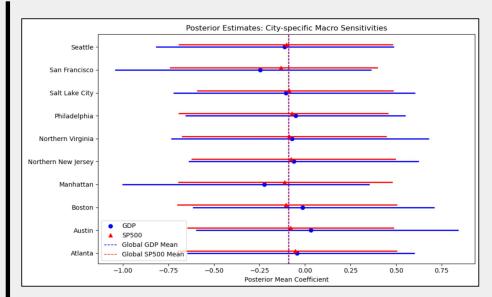

Let
$$\theta$$
 represent all unknown parameters:
$$\theta = \left\{\alpha_j, \beta_j^{GDP}, \beta_j^{SP}, \mu_\alpha, \mu_{\beta,GDP}, \mu_{\beta,SP}, \tau_\alpha, \tau_{\beta,GDP}, \tau_{\beta,SP}, \sigma\right\}$$
 Given the data $D = \{y_i, x_i\}$, the posterior is:
$$p(\theta \mid D) \propto \underbrace{\prod_{i=1}^N \mathcal{N}\left(y_i \mid \alpha_{j[i]} + \beta_{j[i]}^{GDP} x_i^{GDP} + \beta_{j[i]}^{SP} x_i^{SP}, \sigma^2\right)}_{\text{Likelihood}} \times \underbrace{\prod_{j=1}^J \mathcal{N}(\alpha_j \mid \mu_\alpha, \tau_\alpha^2) \cdot \mathcal{N}(\beta_j^{GDP} \mid \mu_{\beta,GDP}, \tau_{\beta,GDP}^2) \cdot \mathcal{N}(\beta_j^{SP} \mid \mu_{\beta,SP}, \tau_{\beta,SP}^2)}_{\text{City-level priors}} \times \underbrace{\mathcal{N}(\mu_\alpha \mid 0, 10^2) \cdot \mathcal{N}(\mu_{\beta,GDP} \mid 0, 5^2) \cdot \mathcal{N}(\mu_{\beta,SP} \mid 0, 5^2)}_{\text{HalfNormal}(\tau_\alpha \mid 5) \cdot \text{HalfNormal}(\tau_{\beta,GDP} \mid 2) \cdot \text{HalfNormal}(\tau_{\beta,SP} \mid 2)}_{\text{Likelihood noise prior}} \times \underbrace{\mathcal{N}(\mu_\alpha \mid 0, 10^2) \cdot \mathcal{N}(\mu_{\beta,GDP} \mid 0, 5^2) \cdot \mathcal{N}(\mu_{\beta,SP} \mid 0, 5^2)}_{\text{Likelihood noise prior}} \times \underbrace{\mathcal{N}(\mu_\alpha \mid 0, 10^2) \cdot \mathcal{N}(\mu_{\beta,GDP} \mid 0, 5^2) \cdot \mathcal{N}(\mu_{\beta,SP} \mid 0, 5^2)}_{\text{Likelihood noise prior}} \times \underbrace{\mathcal{N}(\mu_\alpha \mid 0, 10^2) \cdot \mathcal{N}(\mu_{\beta,GDP} \mid 0, 5^2)}_{\text{Likelihood noise prior}} \times \underbrace{\mathcal{N}(\mu_\alpha \mid 0, 10^2) \cdot \mathcal{N}(\mu_{\beta,GDP} \mid 0, 5^2)}_{\text{Likelihood noise prior}} \times \underbrace{\mathcal{N}(\mu_\alpha \mid 0, 10^2) \cdot \mathcal{N}(\mu_{\beta,GDP} \mid 0, 5^2)}_{\text{Likelihood noise prior}} \times \underbrace{\mathcal{N}(\mu_\alpha \mid 0, 10^2) \cdot \mathcal{N}(\mu_{\beta,GDP} \mid 0, 5^2)}_{\text{Likelihood noise prior}} \times \underbrace{\mathcal{N}(\mu_\alpha \mid 0, 10^2) \cdot \mathcal{N}(\mu_{\beta,GDP} \mid 0, 5^2)}_{\text{Likelihood noise prior}} \times \underbrace{\mathcal{N}(\mu_\alpha \mid 0, 10^2) \cdot \mathcal{N}(\mu_{\beta,GDP} \mid 0, 5^2)}_{\text{Likelihood noise prior}} \times \underbrace{\mathcal{N}(\mu_\alpha \mid 0, 10^2) \cdot \mathcal{N}(\mu_{\beta,GDP} \mid 0, 5^2)}_{\text{Likelihood noise prior}} \times \underbrace{\mathcal{N}(\mu_\alpha \mid 0, 10^2) \cdot \mathcal{N}(\mu_{\beta,GDP} \mid 0, 5^2)}_{\text{Likelihood noise prior}} \times \underbrace{\mathcal{N}(\mu_\alpha \mid 0, 10^2)}_{\text{Likelihood noise prior}} \times \underbrace{\mathcal{N}(\mu_\alpha \mid 0, 10^2)$$

Modeling Insight – Shrinkage:

- Extreme values (ex: Manhattan's GDP effect) are pulled toward the average
- Partial pooling reduces overconfidence and better reflects uncertainty

Macroeconomic Impacts:

- GDP has a weak but positive effect on rents
- Stock market gains have a positive influence

City-Specific Dynamics:

- San Francisco and Manhattan: Rent trends are less tied to GDP (possibly inverse)
- Phoenix, Atlanta, Houston: More responsive to economic growth
- Stock market effects are broadly positive and more consistent across cities
